Testing the map's location, on Windows

The Blood Bank Locator places your pin **without a click** — a member at their registered address, an officer at their blood bank — and then asks the browser for **live GPS**. Browsers only share GPS with secure pages (`https://` or `localhost`), and Local serves sites on plain `http://`, so this checklist tests both: first on http (W1–W4), then after trusting Local's certificate (W5–W10). Use **Chrome** or **Edge**.

BEFORE YOU START

- Start your site in Local. Replace `<your-site>` below with your Local site's domain (shown under the site name in Local), e.g. `http://4amicms.local/bloodlink/`.
- You'll need a member with an address on My Profile, a member without one, an officer and the admin.
- Location only works over the internet connection the PC is on — map tiles and routes also need internet.

Checklist

W1–W10

On plain http W1–W4

W1 Member is pinned without a click (plain http)

WHO Member with an address on their profile START Sidebar → **Nearby Banks**

DO

1. Sign in as a member whose My Profile has an address, open Nearby Banks, and don't click anything.

EXPECT

- ✓ The blue pin appears at "Your registered address (...)", the banks are ranked nearest-first and the shortest road route to the nearest bank is drawn in blue with "x km · y min".
- ✓ An amber note says "Live GPS isn't available on this address" because the page is on `http://`. No location prompt appears.

W2 Officer is pinned at their bank

WHO Officer START Sidebar → **Geo-Map**

DO

1. Sign in as a hospital officer and open Geo-Map.

EXPECT

✓ The pin is at "Your blood bank (...)"; their own bank is ranked first at 0 km, with the other banks after it by distance.

W3 No saved location

WHO Admin, or a member with no address START Sidebar → **Geo-Map** / **Nearby Banks**

DO

1. Open the map as the admin, then as a member whose profile has no address.

EXPECT

✓ No pin is placed; the note says to drop the pin by clicking the map. Clicking the map places the pin and routes to the nearest bank.

W4 "Use my location" on plain http

WHO Any role START the map, on `http://`

DO

1. Click **Use my location**.

EXPECT

✓ No browser prompt; the amber note explains that browsers only share GPS with secure (https) pages, and the saved location stays.

After trusting the certificate (https) W5–W10

W5 Trust Local's certificate → the map switches to https by itself

WHO Tester START the Local app

DO

1. In Local, select your site → **Overview** → next to **SSL** click **Trust**, and answer **Yes** to the Windows prompts (certificate install / administrator permission).
2. Close every Chrome or Edge window, then open the browser again.
3. Open `http://<your-site>.local/bloodlink/geo_map.php` (the plain http address).

EXPECT

✓ Within a second the address bar changes to `https://…/geo_map.php?locate=1`, with a padlock and no warning, and you are still signed in.

✓ If you see "Your connection isn't private", the certificate isn't trusted yet: repeat the first two steps. Use Chrome or Edge for this test — Firefox keeps its own certificate list and may still warn.

W6 Live GPS on https

WHO Any role START the map, on `https://`

DO

1. In Windows **Settings → Privacy & security → Location**, turn on **Location services**, **Let apps access your location** and **Let desktop apps access your location**.
2. Reload the map; when the browser asks to know your location, click **Allow**.

EXPECT

- ✓ The pin moves from the saved address to "Your current location" with a pale blue accuracy ring, the banks re-rank and the route is redrawn. The amber note disappears.
- ✓ A laptop on Wi-Fi is usually placed within tens to a few hundred metres; a desktop on a cable may not be located at all — that is W9's message, not a failure of BloodLink.

W7 Simulate a location (works on any PC)

WHO Tester START the map, on `https://`, Chrome or Edge

DO

1. Press **F12** → the ⋮ menu at the top right of DevTools → **More tools** → **Sensors**.
2. Under **Location** choose **Other...** and enter latitude `11.0855`, longitude `7.7199` (Zaria); click **Use my location** on the page.
3. Change it to `10.5222`, `7.4383` (Kaduna city centre) and click **Use my location** again.

EXPECT

- ✓ Zaria: the pin moves there, ABU Teaching Hospital is first and a short road route (a few km) is drawn.
- ✓ Kaduna: the pin moves to the city centre and the Kaduna banks come first.

W8 Location blocked in the browser

WHO Any role START the map, on `https://`

DO

1. Click the padlock / site-information icon at the left of the address bar → **Location** → **Block**; reload the page.
2. Set it back to **Allow** afterwards.

EXPECT

- ✓ The amber note says "Location is blocked", explains how to allow it in the browser and in Windows Settings, and the pin stays at the saved address.

W9 Windows location turned off

WHO Tester START Windows Settings

DO

1. Turn **Location services** off in Windows Settings; reload the map.
2. Turn it back on afterwards.

EXPECT

- ✓ The note says the location couldn't be found (or is blocked) and gives the Windows steps — **Settings → Privacy & security → Location**. The saved-address pin and route are still shown.

W10 The pin still works after GPS

WHO Any role START the map

DO

1. Drag the blue pin somewhere else; click the map; pick a different bank in the list; move the pin again.

EXPECT

✓ Each move re-ranks the banks and re-routes. Once you pick a bank yourself, moving the pin keeps routing to that bank.

Notes

If something doesn't match

WHAT YOU SEE	WHAT IT MEANS / WHAT TO DO
The page stays on `http://` after W5	The certificate isn't trusted by the browser yet. Click **Trust** in Local again, accept the Windows prompts, and fully restart the browser (close it from the system tray too).
"Your connection isn't private" on `https://`	Same cause. Don't click through the warning — the page won't count as secure, and GPS still won't be offered.
No location prompt on https	The site was blocked earlier: padlock icon → **Location** → **Allow** (or **Reset permission**), then reload.
Prompt allowed, but "couldn't work out where you are"	Windows location is off, or the PC can't be located (no Wi-Fi). Turn on the three Windows switches in W6, or use W7 to simulate a location.
Pin is on the wrong side of town	Wi-Fi and IP location can be off by a few kilometres on a desktop. Drag the pin; the route follows it.
No pin at all as a member	That member has no map coordinates — add an address under **My Profile** and save.

ANOTHER WAY TO GET A SECURE PAGE, WITHOUT A CERTIFICATE

`localhost` also counts as secure. If your version of Local has it, **Preferences → Advanced → Router mode → localhost** serves sites at `http://localhost:<port>`, where GPS works without trusting anything. It changes the address of **every** Local site, so switch it back to **Site domains** when you're done.
